

Improving eligibility propagation using Izhikevich neurons in a multilayer RSNN.

Presentation 5: Evaluation meeting 1

Werner van der Veen

December 8, 2020

A quick project overview

Task: using eligibility propagation to classify phonemes.

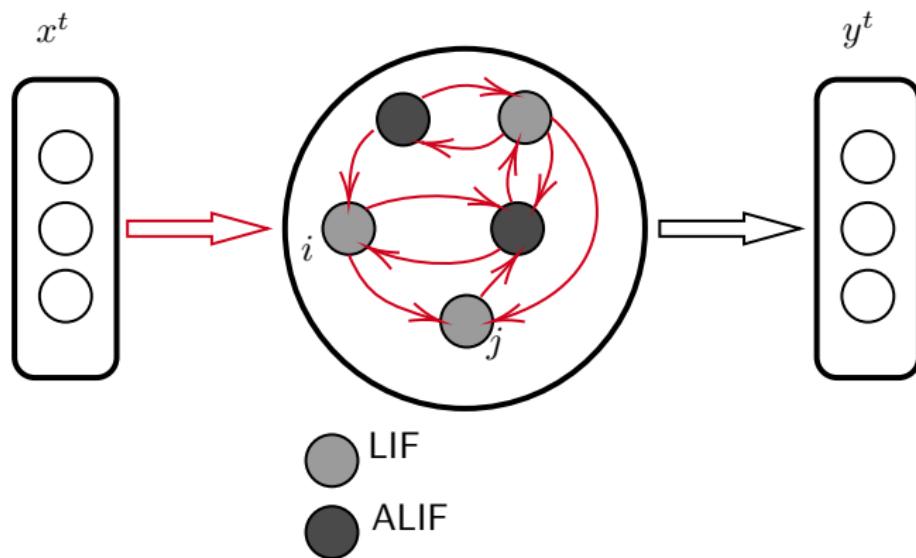

Challenges:

- Desired bio-plausibility requires online and local learning rules.
- Spiking and recurrent network: no good learning algorithm yet.

My own contribution: investigate the benefits of

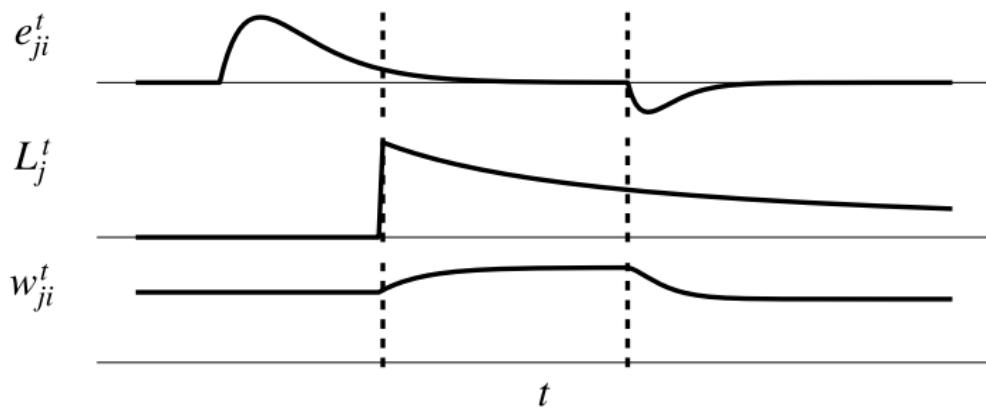

- stacking multiple recurrent layers;
- using Izhikevich neurons;
- various regularization methods.

Original network architecture

The e-prop learning algorithm – Main equation

$$\frac{dE}{dW_{ji}} = \sum_t L_j^t \cdot e_{ji}^t$$

The e-prop learning algorithm – basic equations (L_j^t)

$$\frac{dE}{dW_{ji}} = \sum_t L_j^t \cdot e_{ji}^t$$

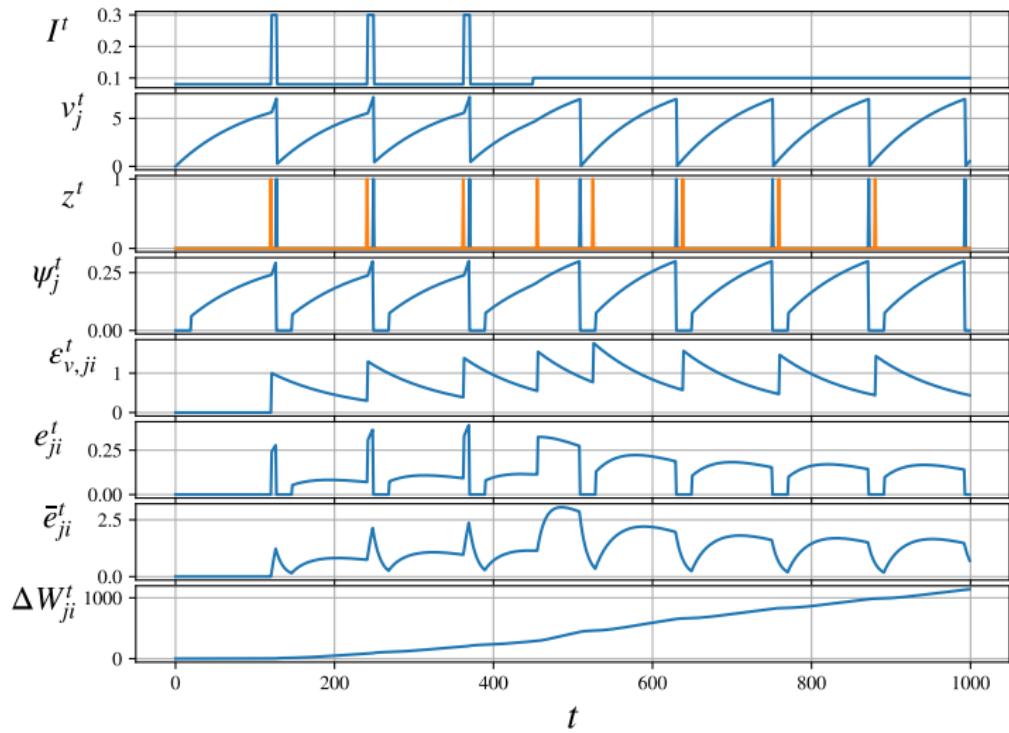

$$\begin{aligned} L_j^t &\stackrel{\text{def}}{=} \frac{\partial E}{\partial z_j^t} \\ &= \sum_k B_{jk} (\pi_k^t - \pi_k^{*,t}) \end{aligned}$$

(proof omitted for brevity)

The e-prop learning algorithm – basic equations (e_{ji}^t)

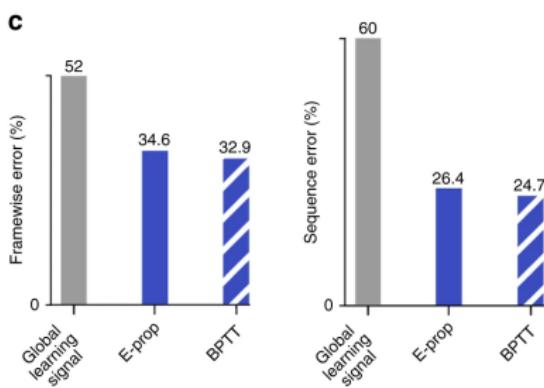

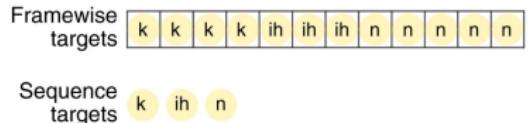

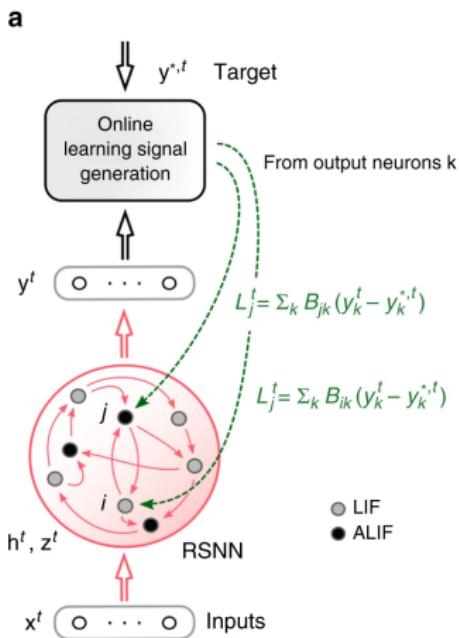

$$\begin{aligned} e_{ji}^t &\stackrel{\text{def}}{=} \frac{\partial z_j^t}{\partial \mathbf{h}_j^t} \underbrace{\sum_{t' \leq t} \frac{\partial \mathbf{h}_j^{t'}}{\partial \mathbf{h}_j^{t-1}} \cdots \frac{\partial \mathbf{h}_j^{t'+1}}{\partial \mathbf{h}_j^{t'}} \cdot \frac{\partial \mathbf{h}_j^{t'}}{\partial W_{ji}}}_{\stackrel{\text{def}}{=} \boldsymbol{\epsilon}_{ji}^t} \\ &= \psi_j^t \bar{z}_i^{t-1} \quad (\text{for LIF neurons in Bellec et al.}) \end{aligned}$$

The e-prop learning algorithm – Original LIF

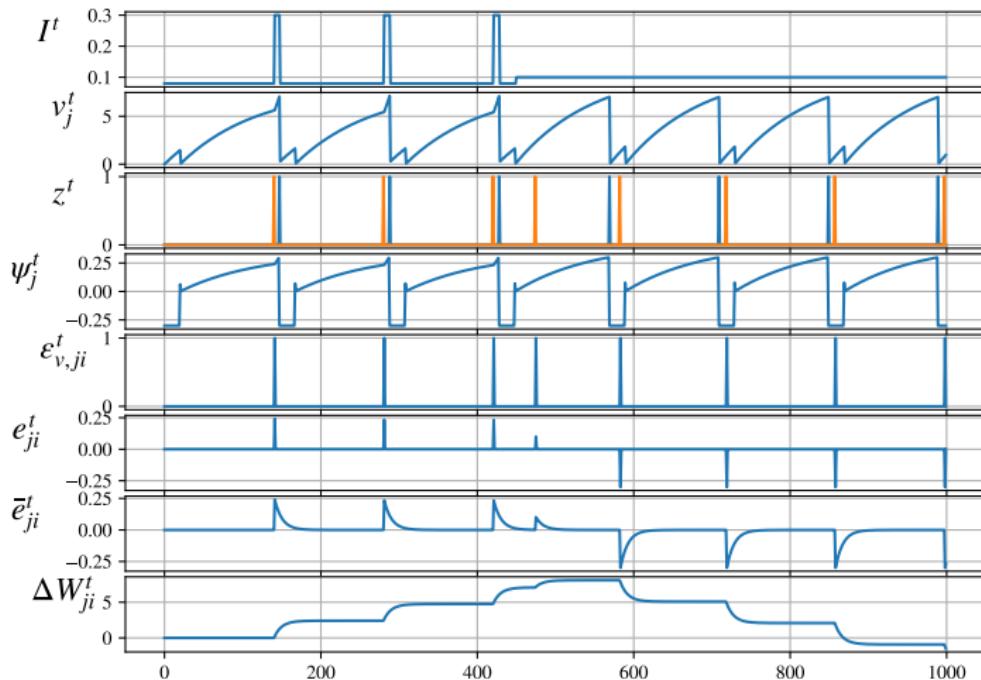

Previous results

Bellec, G., Scherr, F., Subramoney, A., Hajek, E., Salaj, D., Legenstein, R., & Maass, W. (2020). A solution to the learning dilemma for recurrent networks of spiking neurons.

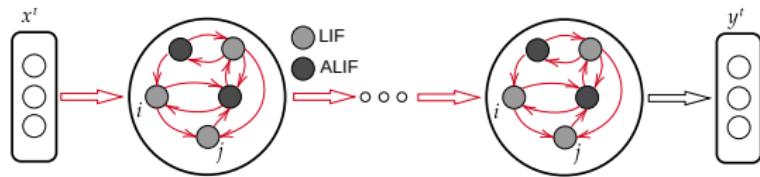

The e-prop learning algorithm – STDP-corrected LIF

Traub, M., Butz, M. V., Baayen, R. H., & Otte, S. (2020, September). Learning Precise Spike Timings with Eligibility Traces. In International Conference on Artificial Neural Networks (pp. 659-669). Springer, Cham.

My proposed contribution

- Implement the algorithm in a *multi-layer* SRNN.

- Evaluate model designs such as neuron type (e.g. Izhikevich); synaptic delay; and regularization such as metaplasticity and synaptic scaling.

Work done so far

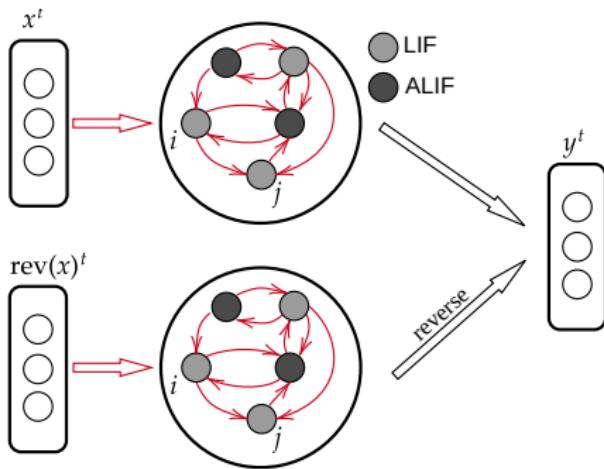

Implement Bellec's model with

- 1-layer e-prop RSNN with ALIF neurons;
- TIMIT conversion to 13 MFCCs and their first and second derivatives;
- L^2 and firing rate regularization;
- Adam optimizer;
- Bidirectional network.

Obtain Bellec's performance;

Analyze effects of

- N-layered network;
- Izhikevich neurons;
- Metaplasticity;
- Synaptic scaling;
- Traub's fix;
- Synaptic delays.

Work since last meeting

- Implemented bidirectional network;
- Exponentially improved space complexity by optionally not tracking synapse variables over time or epochs;
- Implemented Bayesian hyperparameter optimization using Gaussian processes;
- Worked on synaptic delay but not yet finished.

Current observations

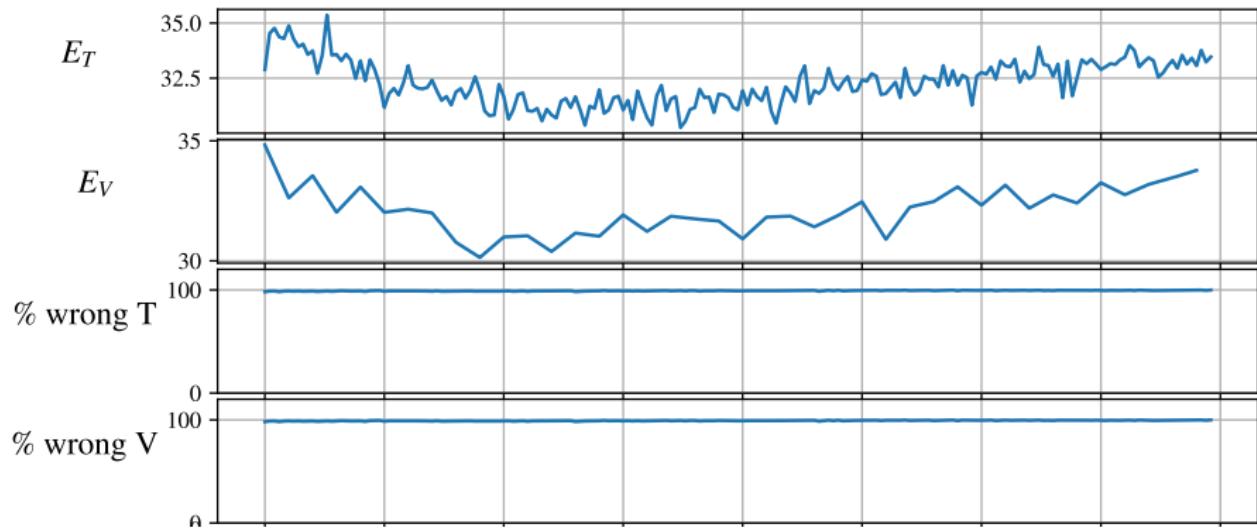

-

$$\lim_{e \rightarrow \infty} W_{\text{out}}^e = \mathbf{0}$$

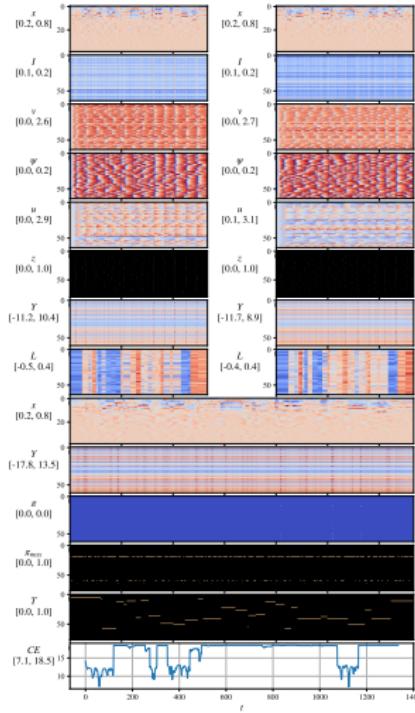

$$\lim_{e \rightarrow \infty} b_{\text{out}}^e = \mathbf{0}$$

- Spike frequency normal but heavily affected by weight initialization.
Currently finding good rule of thumb for good scaling per layer. Weights in uniform range of $[0, \frac{C}{N}]$ work well, where N is number of afferent connections.

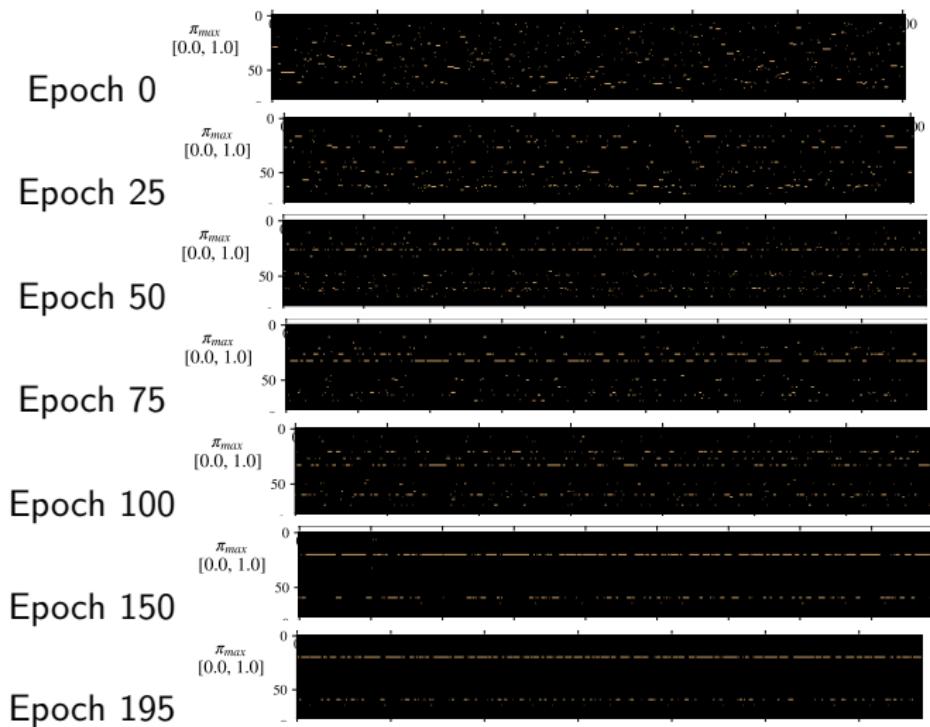

Typical results (Undesired pulsation)

Typical results (Bellec reproduction attempt)

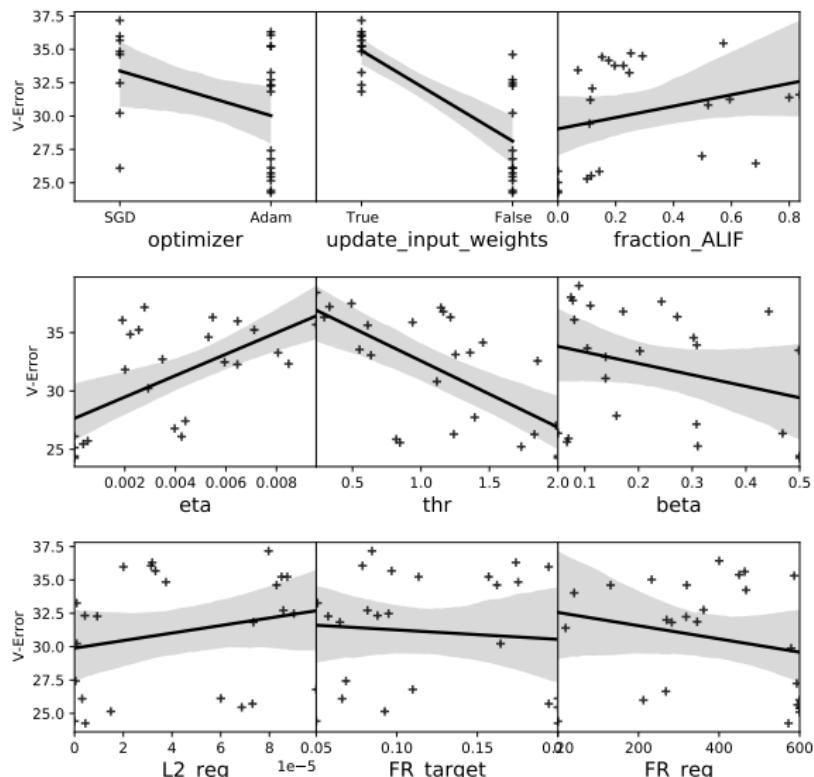

Typical results (latest Bellec run)

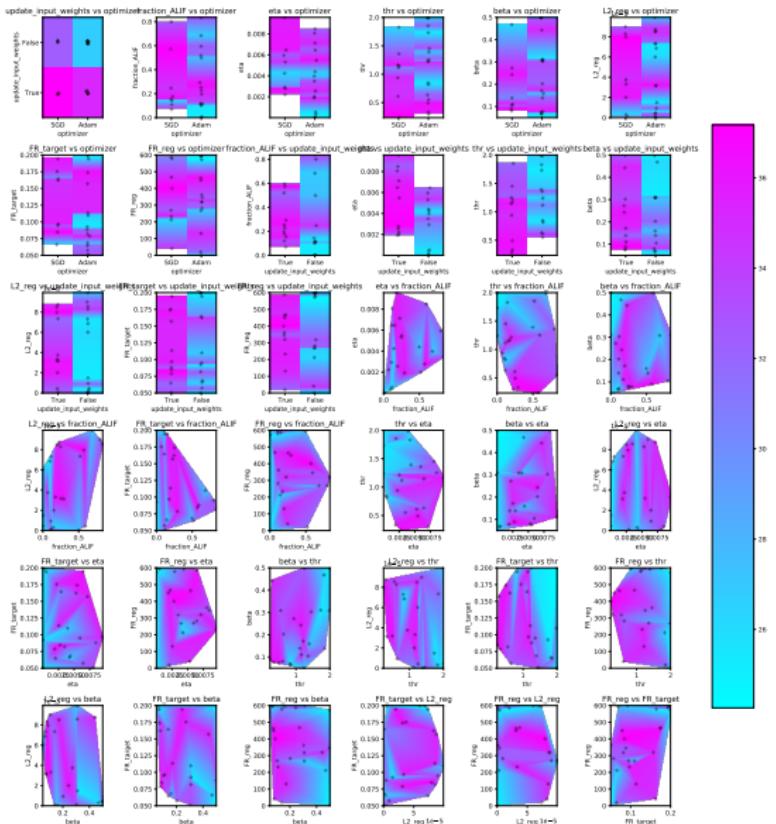

Current configuration toolbox

- E-prop type (random, symmetric, adaptive) (for updating B_j^t)
- Optimizer (Adam, SGD)
- Traub fix
- Fraction ALIF
- Uni- or bidirectional
- Target delay
- Various e-prop model constants
- Initial weight scaling
- Weight decay
- L^2 regularization
- Firing rate regularization (strength & target Hz)
- Weight dropout rate
- Adam optimizer constants
- Number of layers
- Nodes per layer
- Input repeats
- Batch size

Hyperparameter sweep results

My questions

- Initial weights scaling? Freezing initial weights?
- Thesis template? (.tex)
- Any questions or suggestions?
